#### fork: Creating New Processes

- int fork(void)
  - creates a new process (child process) that is identical to the calling process (parent process)
  - returns 0 to the child process
  - returns child's process ID (pid) to the parent process

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

■ Fork is interesting (and often confusing) because it is called *once* but returns *twice* 

#### Process n

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

#### Process n

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

#### Child Process m

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

pid = m

#### Process n

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

#### Child Process m

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

#### Process n

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

#### Child Process m

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
   printf("hello from child\n");
} else {
   printf("hello from parent\n");
}
```

#### Process n

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

#### Child Process m

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
    printf("hello from child\n");
} else {
    printf("hello from parent\n");
}
```

```
pid_t pid = fork();
if (pid == 0) {
   printf("hello from child\n");
} else {
   printf("hello from parent\n");
}
```

hello from parent

Which one is first?

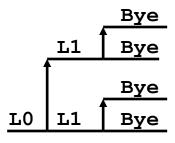

hello from child

- Parent and child both run same code
  - Distinguish parent from child by return value from fork
- Start with same state, but each has private copy
  - Including shared output file descriptor
  - Relative ordering of their print statements undefined

```
void fork1()
{
    int x = 1;
    pid_t pid = fork();
    if (pid == 0) {
        printf("Child has x = %d\n", ++x);
    } else {
        printf("Parent has x = %d\n", --x);
    }
    printf("Bye from process %d with x = %d\n", getpid(), x);
}
```

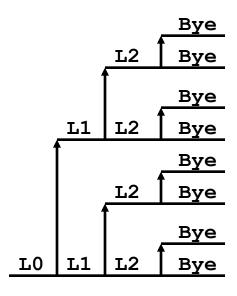

```
void fork2()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("Bye\n");
}
```

```
void fork2()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("Bye\n");
}
```

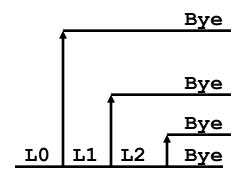

```
void fork3()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("L2\n");
    fork();
    printf("Bye\n");
}
```

```
void fork3()
{
    printf("L0\n");
    fork();
    printf("L1\n");
    fork();
    printf("L2\n");
    fork();
    printf("Bye\n");
}
```

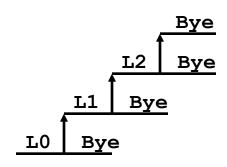

```
void fork4()
{
    printf("L0\n");
    if (fork() != 0) {
        printf("L1\n");
        if (fork() != 0) {
            printf("L2\n");
            fork();
        }
     }
    printf("Bye\n");
}
```

```
void fork4()
{
    printf("L0\n");
    if (fork() != 0) {
        printf("L1\n");
        if (fork() != 0) {
            printf("L2\n");
            fork();
        }
    }
    printf("Bye\n");
}
```

```
void fork5()
{
    printf("L0\n");
    if (fork() == 0) {
        printf("L1\n");
        if (fork() == 0) {
            printf("L2\n");
            fork();
        }
     }
    printf("Bye\n");
}
```

```
void fork5()
{
    printf("L0\n");
    if (fork() == 0) {
        printf("L1\n");
        if (fork() == 0) {
            printf("L2\n");
            fork();
        }
     }
    printf("Bye\n");
}
```

## exit: Ending a process

- void exit(
  - status)

exits a process

• Nactremently return with status 0

#### **Zombies**

#### Idea

- When process terminates, still consumes system resources
  - Various tables maintained by OS
- Called a "zombie"
  - That is, a living corpse, half alive and half dead

#### Reaping

- Performed by parent on terminated child (horror movie!)
- Parent is given exit status information
- Kernel discards process

#### What if parent doesn't reap?

- If any parent terminates without reaping a child, then child will be reaped by init process
- So, only need explicit reaping in long-running processes
  - e.g., shells and servers

# Zombie Example

```
linux> ./forks 7 &
[1] 6639
Running Parent, PID = 6639
Terminating Child, PID = 6640
linux> ps
 PTD TTY
                  TIME CMD
 6585 ttyp9
             00:00:00 tcsh
 6639 ttyp9 00:00:03 forks
 6640 ttyp9 00:00:00 forks <defunct>
 6641 ttyp9
              00:00:00 ps
linux> kill 6639
[1] Terminated
linux> ps
 PID TTY
                  TIME CMD
 6585 ttyp9
              00:00:00 tcsh
 6642 ttyp9
              00:00:00 ps
```

- ps shows child process as "defunct"
- Killing parent allows child to be reaped by init

# Non-terminating Child Example

```
linux> ./forks 8
Terminating Parent, PID = 6675
Running Child, PID = 6676
linux> ps
 PID TTY
                   TIME CMD
 6585 ttyp9
               00:00:00 tcsh
 6676 ttyp9
               00:00:06 forks
 6677 ttyp9
               00:00:00 ps
linux> kill 6676
linux> ps
 PID TTY
                   TIME CMD
 6585 ttyp9
               00:00:00 tcsh
 6678 ttyp9
               00:00:00 ps
```

- Child process still active even though parent has terminated
- Must kill explicitly, or else will keep running indefinitely

# Synchronization!

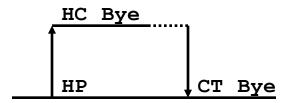

#### wait: Synchronizing with Children

- int wait(int \*child\_status)
  - suspends current process until one of its children terminates
  - return value is the pid of the child process that terminated
  - if child\_status != NULL, then the object it points to will be set to a status indicating why the child process terminated

#### wait: Synchronizing with Children

```
void fork9() {
  int child_status;

if (fork() == 0) {
    printf("HC: hello from child\n");
}
else {
    printf("HP: hello from parent\n");
    wait(&child_status);
    printf("CT: child has terminated\n");
}
printf("Bye\n");
exit();
}
```

#### wait() Example

- If multiple children completed, will take in arbitrary order
- Can use macros WIFEXITED and WEXITSTATUS to get information about exit status

```
void fork10()
{
   pid t pid[N];
    int i;
    int child status;
    for (i = 0; i < N; i++)
       if ((pid[i] = fork()) == 0)
           exit(100+i); /* Child */
    for (i = 0; i < N; i++) {
       pid t wpid = wait(&child status);
       if (WIFEXITED(child status))
           printf("Child %d terminated with exit status %d\n",
                  wpid, WEXITSTATUS(child status));
       else
           printf("Child %d terminated abnormally\n", wpid);
```

#### waitpid(): Waiting for a Specific Process

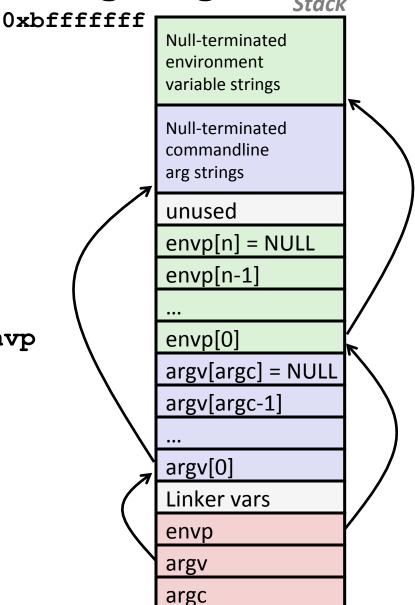

- waitpid(pid, &status, options)
  - suspends current process until specific process terminates
  - various options (that we won't talk about)

```
void fork11()
   pid t pid[N];
    int i;
    int child status;
    for (i = 0; i < N; i++)
       if ((pid[i] = fork()) == 0)
           exit(100+i); /* Child */
    for (i = 0; i < N; i++) {
       pid t wpid = waitpid(pid[i], &child status, 0);
       if (WIFEXITED(child status))
           printf("Child %d terminated with exit status %d\n",
                  wpid, WEXITSTATUS(child status));
       else
           printf("Child %d terminated abnormally\n", wpid);
```

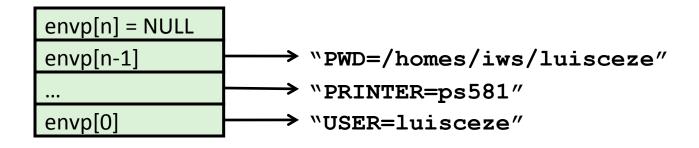

#### execve: Loading and Running Programs

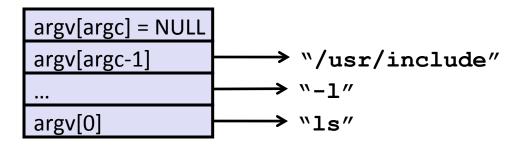

```
int execve(
    char *filename,
    char *argv[],
    char *envp
)
```

- Loads and runs
  - Executable filename
  - With argument list argv
  - And environment variable list envp
- Does not return (unless error)
- Overwrites process, keeps pid
- Environment variables:
  - "name=value" strings

#### execve: Example

#### Summary

#### Exceptions

- Events that require non-standard control flow
- Generated externally (interrupts) or internally (traps and faults)

#### Processes

- At any given time, system has multiple active processes
- Only one can execute at a time, however,
- Each process appears to have total control of the processor + has a private memory space

# Summary (cont'd)

- Spawning processes
  - Call to fork
  - One call, two returns
- Process completion
  - Callexit
  - One call, no return
- Reaping and waiting for Processes
  - Call wait or waitpid
- Loading and running Programs
  - Call execl (or variant)
  - One call, (normally) no return
